INTRODUCTION

Advances in bioprinting have enabled synthetic tissue, organ, and skin construction via additive manufacturing techniques [1]. The most common bioprinting approach involves depositing hydrogel solutions embedded with bio-inks via pressure driven syringes [2] or via inkjetting [3]. Inkjet approaches are a viable alternative since they do not damage the cell yet permit high-speed control. Prior art has demonstrated the benefits of bioprinting for tissue engineering [4]. However, prior art has emphasized open loop deposition on planar, stationary surfaces. This is sufficient for laboratory settings where culture dishes are utilized or subjects can be sedated and the anatomy fixed. As envisioned in [5], some clinical settings may benefit from depositing bio-inks onto moving anatomy such as an unfixed hand of a burn patient that must move during therapy to maintain range of motion for skin grafts. Alternatively, a hand-held precision bioprinting tool (Fig. 1 Top) may move relative to patient anatomy or be scaled down for use in laparoscopic surgery (Fig. 1 Middle) and contend with unpredictable anatomical motion.

The gap in prior art has been the demonstration of an additive manufacturing technique capable of depositing and adhering viable biomaterials directly onto unconstrained, non-planar, moving anatomy. The objective of this paper is to demonstrate the feasibility of robotically depositing and adhering bioprinting-compatible materials. We evaluated two bio-inks for their accuracy and adhesion during bioprinting directly onto moving human anatomy.

MATERIALS AND METHODS

As in [5], the Leap Motion (Leap Inc, Mountain View CA) was used to track the human hand at 120Hz and a Nordson EFD PICO Pulse piezo jetting system was used to propel the fluid onto the hand when it was in the correct position. Here, the system ran on a Linux PC using the Robot Operating System (ROS), with a graphical display of the current position of the hand relative to the remaining pixels in the pattern, a suggested target highlighted (Fig. 2), and a height bar showing the acceptable distance from the hand to the jet (~1cm). The system allowed either the user to move their hand relative to the system, or an operator to move the system relative to the user’s hand.

Two hydrogels were used. These hydrogels are biocompatible and are used as scaffolds for bioprinting [6]. The first consisted of Sodium Alginate that was deposited onto the hand, followed by an aqueous Calcium Chloride solution airbrushed onto the hand to crosslink the Alginate (as in [5]).

A second hydrogel was synthesized with deionized water containing 10% GelMA (gelatin methacrylate) and 0.5% LAP (lithium phenyl-2,4,6-trimethylbenzoyl-phenophosphate) as a photoinitiator to allow use of a 405nm flashlight to crosslink between layers. This natural bio-ink is also proven to be compatible with a variety of cell types [7].

Blue food dye was used to color the hydrogels to allow for a computer vision-based evaluation of the 2D accuracy from scans of the finished gels on a flatbed scanner at 600 DPI (Fig. 4). The scans were then compared to the target template (Fig. 3) to determine...
True Positive (TP), False Negative (FN) and False Positive (FP) areas. These values were then used to determine True Positive Rate (TPR), False Negative Rate (FNR) and False Discovery Rate (FDR) to provide metrics that were independent of the template image.

RESULTS
The robotic system was able to detect and track the subject’s hands with sufficient speed. The user was able to ink at 1.8 pixels per second, leading to an average layer time of 182 seconds.

The Calcium Alginate provided moderate layer to layer adhesion and poor adhesion to the skin of the hand, being easily peeled away by even stretching the underlying skin. The GelMA hydrogel provided good layer to layer adhesion, as well as good adhesion to the underlying skin. Table 1 shows True Positive Rate (TPR) and False Discovery Rate (FDR) for both gels.

Tab. 1 Comparison of Calcium Alginate to GelMA Hydrogel

DISCUSSION
Both proposed hydrogels show promise as bio-inks for additive manufacturing on moving anatomy, however both need further development. The Calcium Alginate’s requirement of the aqueous Calcium Chloride caused the gel to run, and the crosslinking was incomplete leading to poor layer adhesion. The GelMA hydrogel became too warm in the PICO Pulse thus becoming too liquid, causing the gel to run and not hold shape, leading to a large False Positive area. If this were adequately addressed (eg by controlling viscosity via temperature or an additive like glycerol) GelMA would prove superior to Alginate for this application.
